Molecular Shape: The shape of some covalent molecule is described in the form of a Lewis structure. It contains some spatial distribution of shared valence electron pairs in the form of covalent bonds between certain connected atoms. For many simple molecules there is a single central atom bonded to multiple different peripheral atoms. Based on VSEPR theory, the geometry around the central ...

Molecular Geometry: According to the Valence Shell Electron Repulsion theory, electrons (bonding and non-bonding electrons) arrange themselves around an atom in a manner so that the repulsion between them is at a minimum. This behavior of electrons primarily determines the geometry of molecules which in return influence their polarity. Answer and Explanation: 1

Valence Electrons Valence electrons are the electrons that are situated in the outermost shell of an atom. The valence electrons of each atom can be used to predict bonding and geometry of molecules as the atoms tend to obey the octet rule. the octet rule states that each atom tends to lose or gain electrons to become stable in order to fill its valence shell with 8 electrons. Atoms can bond ...
